The Workflow State Machine

0.10verview document

by Andreas Hartmann

1. Invoking a Transition

When an event e is invoked on a workflow instance I, the following algorithm is executed:

- The current state *scurrent* is determined.
- The transition t from scurrent to snext which has the event e is determined.
 - If *t* is not exactly defined, an exception is thrown.
 - All conditions of *t* are validated.
 - If all conditions are complied, the transition *t* fires:
 - All assignments of *t* are executed.
 - The workflow instance *I* is advanced to the state *snext*.
